ABSTRACT

Insomnia is a common sleep disorder frequently occurring in chronic alcoholic patients. Neurobiological basis of insomnia, as well as of alcoholism, is associated with disrupted functions of the main neurotransmitter systems, including the serotonin (5-hydroxytryptamine, 5-HT) system. Blood platelets are considered a limited peripheral model for the central 5-HT neurons, since both platelets and central 5-HT synaptosomes have similar dynamics of 5-HT. Platelet 5-HT concentration and platelet monoamine oxidase type B (MAO-B) are assumed to represent biomarkers for particular symptoms and behaviors in psychiatric disorders. The hypothesis of this study was that platelet 5-HT concentration and platelet MAO-B activity will be altered in chronic alcoholic patients with insomnia compared to comparable values in patients without insomnia. The study included 498 subjects: 395 male and 103 female medication-free patients with alcohol dependence and 502 healthy control subjects: 325 men and 177 women. The effects of early, middle and late insomnia (evaluated using the Hamilton Depression Rating Scale), as well as sex, age and smoking on platelet 5-HT concentration and platelet MAO-B activity were evaluated using one-way ANOVA and multiple regression analysis by the stepwise method. Platelet 5-HT concentration, but not platelet MAO-B activity, was significantly reduced in alcoholic patients with insomnia compared to patients without insomnia. Multiple regression analysis revealed that platelet 5-HT concentration was affected by middle insomnia, smoking and sex, while platelet MAO activity was affected only by sex and age. The present and previous data suggest that platelet 5-HT concentration might be used, after controlling for sex and smoking, as a biomarker for insomnia in alcoholism, PTSD and in rotating shift workers.

Patients with chronic alcoholism frequently experience sleep disturbances such as insomnia, disrupted sleep, frequent episodes of wakefulness, early wakening, and the reduced quality of life [6,30]. Insomnia is present in 36–72% of alcoholic patients [1], since chronic alcoholism affects sleep quality, and sleep is fragmented and restless [1]. Insomnia can be classified into early, middle and late according to the Hamilton Depression Rating Scale (HDRS) [11]. Neurobiological basis of insomnia, as well as of alcoholism, is associated with disrupted functions of the main

neurotransmitters systems such as serotonin (5-hydroxytryptamine, 5-HT), noradrenalin and histamine. Wakefulness is related to increased 5-HT activity from dorsal raphe [33]. Altered function of the 5-HT system is associated with development of alcoholism, alcohol addiction, alcohol abuse [15,29], and sleep apnea [18], insomnia [34], arousal, sleep-waking states, vigilance behaviors, synchronization of the biological clock and circadian rhythm [34], while sleep disturbances are affected by antidepressants [1]. Insomnia is related to mood instabilities, craving, alcoholic relapse and heavy drinking in chronic alcoholic patients [6]. Prolonged insomnia may lead to self medication with alcohol and chronic alcoholism, while, on the other hand, toxic effects of alcohol in the brain of chronic alcoholics may lead to insomnia [6,30]. Blood platelets are considered as a non-invasive and inexpensive peripheral model for the studies of the central 5-HT neurons, since both platelets and central 5-HT synaptosomes have similar uptake, storage,

Abbreviations: HDRS, Hamilton Depression Rating Scale; 5-HIAA, 5-hydroxyindolacetic acid; MAO-B, monoamine oxidase type B; 5-hydroxytryptamine 5-HT, serotonin; 5-HTTLPR, serotonin transporter polymorphism.

release and metabolism of 5-HT [7,12]. Platelet 5-HT concentration has been proposed as a marker of the central serotonergic function [8,10] and a biomarker for particular symptoms and behaviors in psychiatric disorders [35], although this proposal has also been challenged [20]. Platelet monoamine oxidase type B (MAO-B) has similar biochemical and pharmacological characteristics with the brain MAO-B [22], and was proposed as a marker for the central serotonergic system [22]. Altered platelet MAO-B activity was associated with different psychopathologies and personality traits, vulnerability to drug-abuse, addiction, social mal-adaptation, and dysinhibitory psychopathology [22]. Lower concentration of platelet 5-HT has been demonstrated in chronic alcoholic patients compared to healthy control subjects [23,26,31], while lower [22], as well as unaltered [25] platelet MAO-B activity was found in alcoholic compared to control subjects. Rotating shift workers with sleep disturbances had lower platelet 5-HT concentration compared to day workers [32], while no data evaluating either platelet 5-HT or platelet MAO-B activity and insomnia in alcoholism has been published thus far. Since chronic alcoholics frequently suffer from insomnia [1], and both platelet markers are under the influence of sex and smoking [21,22], the hypothesis of the study was that platelet 5-HT and MAO-B would differ between patients with chronic alcoholism with or without insomnia. The aim of the study was to evaluate platelet 5-HT concentration and platelet MAO-B activity in alcoholic patients subdivided according to the smoking status, sex and presence and/or absence of early, middle or late insomnia.

The study included 498 subjects: 395 male (49.5 years old, range 23–77) and 103 female (52.5 years old, range 23–84) medication-free patients with chronic alcoholism. The diagnosis of alcohol dependency was done using the Structured Clinical Interview for DSM-IV [9] based on DSM-IV criteria [5]. The comparative healthy control group consisted of 502 subjects: 325 male (45.0 years old, range 23–90) and 177 female (55.6 years old, range 23–89) medication-free subjects, with no personal or family history of psychopathology and/or substance abuse or dependence, no hepatic or renal disorders, and alcohol-free for at least 24 h. Patients were admitted into Psychiatric Hospital Vrapce due to the withdrawal syndrome related to alcohol dependency. Since most of the patients were acutely intoxicated with alcohol, the interview and the sampling were done at least 12 h after the admission at the department, when the patients were sober, with their full cooperation and adequate understanding. Written informed consent was obtained from all subjects, under procedures approved by the

Ethics Committees of the Psychiatric Hospital Vrapce, and University Hospital Center Zagreb, Zagreb, Croatia. Study has been performed in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki. All subjects were subdivided according to the smoking status (into smokers and non-smokers). Alcoholic patients were subdivided according to the items 4 (early insomnia), 5 (middle insomnia) and 6 (late insomnia) of the HDRS [11] into patients without (with score 0) or with (i.e. with scores 1–2) early, middle or late insomnia; or without and with insomnia (including early, middle and late insomnia). Blood samples (8 ml) were collected into plastic syringes with 2 ml of acid citrate dextrose anticoagulant at 08.00 h. The determination of the platelet 5-HT concentration was done in platelet rich plasma using spectrofluorimetric method, as previously described [24,27]. Platelet protein concentrations were measured by the method according to Lowry et al. [16]. Platelet MAO-B activity was determined spectrofluorimetrically using kynuramine as a substrate by a slight modification of the method developed by Krajl [14], as previously described [23]. The results, expressed as means (standard deviation), were evaluated using one-way analysis of variance (ANOVA) followed by Tukey's test and multiple regression analysis by the stepwise method (with predictor variables of insomnia (none, early, middle, late), smoking (non-smoker, smoker), sex (male, female), and age). The level of significance was set at $p = 0.05$.

Age, platelet 5-HT concentration and platelet MAO-B activity were significantly different (one-way ANOVA and Tukey's test) between alcoholic patients and healthy control subjects subdivided according to the sex and smoking status (Table 1). Male alcoholic smokers were significantly ($p = 0.001$) older than healthy male smokers, while other groups were matched for age. Male ($p = 0.028$) and female ($p = 0.019$) alcoholic smokers had significantly lower platelet 5-HT concentration than healthy male or female smokers, and male or female alcoholic non-smokers had significantly ($p = 0.001$) lower platelet 5-HT values than healthy male or female non-smokers. Platelet MAO-B activity was significantly ($p = 0.005$) higher in male alcoholic smokers compared to male healthy smokers (Table 1).

Early (72 and 71%), middle (68 and 67%) and late (38 and 41%) insomnia occurred at similar frequency in male and female alcoholic patients, respectively (Figs. 1 and 2). To determine the association between the dependent variables such as platelet 5-HT concentration (Fig. 1) or platelet MAO-B activity (Fig. 2), and the potential predictor variables (age, sex, smoking status and the presence or absence of early, middle or late insomnia), multiple regression analyses were conducted separately for patients with or

Fig. 1. Platelet 5-HT concentration (mean \pm SD) in alcoholic patients without insomnia and alcoholic patients with early, middle and late insomnia, subdivided according to the sex and smoking status. Numbers in parentheses are the number of subjects. Statistical evaluation of the data is presented in Table 2. * $p=0.001$ vs. the corresponding smokers; ** $p=0.001$ vs. alcoholic patients without insomnia (multiple regression analysis).

without early, middle and late insomnia (Table 2). Multiple regression analyses for platelet 5-HT (significance shown in Fig. 1) as a dependent variable revealed that: (1) smoking status (but not sex, age or early insomnia) significantly ($p=0.001$) predicted 4.9% of the variance in platelet 5-HT concentration; (2) smoking status and the presence or absence of middle insomnia (but not sex and age) significantly ($p=0.032$) predicted 5.5% of the variance in platelet 5-HT concentration, and (3) smoking status and sex (but not age or late insomnia) significantly ($p=0.044$) predicted 8.8% of differences in 5-HT values. Multiple regression analyses with platelet MAO-B activity (significance shown in Fig. 2) as a dependent variable showed that: (1) sex and age (but not early insomnia or smoking) significantly predicted 4.4% of the variance ($p=0.018$) of the enzyme activity, (2) sex and age (but not middle insomnia or smoking) significantly predicted 5.8% of the variance ($p=0.038$) in platelet MAO-B, and (3) sex, but not age, smoking or late insomnia, significantly ($p=0.005$) predicted 2.9% variance in platelet MAO-B values (Table 2). Our collective data reveal that platelet 5-HT concentration, but not platelet MAO-B activity, was significantly lower in alcoholic patients with middle insomnia.

To further corroborate the significant effect of middle insomnia on dependent variables, multiple regression analyses were used to re-evaluate the influence of the age, sex, smoking status and the presence or absence of insomnia (not subdivided into early, middle or late) on platelet 5-HT concentration or platelet MAO-B activity. Analysis confirmed a significant ($R^2=0.060$; adjusted $R^2=0.057$; $F(2,495)=15.888$; $p=0.001$) effect of the presence of insomnia ($t=-2.019$; $p=0.001$) and smoking ($t=5.315$; $p=0.001$) on platelet 5-HT concentration. In contrast, platelet MAO-B activity was significantly ($R^2=0.041$; adjusted $R^2=0.037$; $F(2,495)=10.519$; $p=0.001$) affected by sex ($t=3.690$; $p=0.001$) and age ($t=2.334$; $p=0.020$), but not by presence or absence of insomnia.

Major findings from our study were: (1) alcoholic patients with insomnia (or explicitly with middle insomnia) had significantly lower platelet 5-HT concentration than alcoholic patients without insomnia; (2) the presence of early, middle or late insomnia did not influence platelet MAO-B activity in alcoholic patients; (3) smoking significantly affected platelet 5-HT concentration, and (4) sex and age significantly affected platelet MAO-B activity.

Patients with chronic alcoholism or alcohol abuse frequently (36–72%) suffer from insomnia [1,6,30]. Central 5-HT regulates arousal states, wakefulness, synchronization of the biological clock and circadian rhythm, and alterations of these behaviors may lead to insomnia and sleep disturbances [4]. Platelet 5-HT concentration was lower in rotating shift workers when compared to day workers [32]. We have found lower platelet 5-HT concentration in alcoholic patients with evident middle insomnia (evaluated using HDRS) in comparison to alcoholic patients without middle insomnia. These results were confirmed by the analysis showing that the presence of insomnia (not subdivided into early, middle and late) was significantly associated with platelet 5-HT concentration. These results are in line with the lower platelet 5-HT values, lower levels of the 5-HT metabolite, 5-hydroxyindolacetic acid (5-HIAA), and higher frequency of the short allele of the serotonin transporter polymorphism (5-HTTLPR) found in workers who work in rotation shifts compared to day workers [32]. The present study did not evaluate the distribution of the 5-HTTLPR variants in alcoholic patients with insomnia, since platelet 5-HT concentration is not affected by the 5-HTTLPR genotypes [27,32]. Although three types of insomnia occurred similarly in male and female patients, our present and previous [28] results show the lack of effect of late insomnia on platelet 5-HT concentration in alcoholic patients, male or female patients

Fig. 2. Platelet MAO-B activity (mean \pm SD) in alcoholic patients without insomnia and alcoholic patients with early, middle and late insomnia, subdivided according to the sex and smoking status. Numbers in parentheses are the number of subjects. Statistical evaluation of the data is presented in Table 2. * $p=0.005$ – 0.001 vs. the corresponding male patients (multiple regression analysis).

From the independent variables calculated in this regression (age, sex, smoking status and the presence or absence of early, middle or late insomnia), those listed in table were significantly associated with platelet 5-HT concentration and platelet MAO activity at the indicated level of significance in the model.

^a Fit of the model: $R^2 = 0.049$; adjusted $R^2 = 0.047$; $df = 1,434$; $F = 22.370$; $p < 0.001$.

on dialysis with chronic renal failure [24], or in male veterans with posttraumatic stress disorder (PTSD) [19]. The differences between the aforementioned studies were that these subjects were not categorized according to the smoking status. Our results concur with our preliminary data showing lower platelet 5-HT concentration in the smaller number of male alcoholics with middle insomnia (who were not subdivided according to the smoking status), and in male PTSD veterans with insomnia and flashbacks [28], compared to groups without sleep disturbances. Platelet 5-HT concentration was not affected by medication, age, comorbid diagnoses or suicidal attempts, since the present study included medication-free alcoholic patients; the effect of age was not significant; and comorbid psychiatric disorders or suicide attempts were reported to be devoid of any significant effect on platelet 5-HT concentration in male or female alcoholic patients [21]. The frequency of smoking was similar between male (60%) and female (56%) alcoholics. The finding that male alcoholic smokers have higher platelet 5-HT concentration than male alcoholic non-smokers agrees with previously published data [21,31]. The lack of clear sex related differences in platelet 5-HT concentration is in contrast with some previous data, presumably due to the fact that alcoholic patients were not subdivided according to the smoking status [23,26,28], but this finding is in line with the previous studies after subdivision according to the smoking status [21]. Reduced platelet 5-HT concentration was found in alcoholic subjects compared to healthy control subjects [21,23,26]; but in addition, the present study confirmed significantly lower platelet 5-HT values in male and female alcoholic smokers and non-smokers compared to corresponding healthy male and female smokers and nonsmokers. This finding stresses the need of subdividing data according to the smoking status, since smoking significantly affected platelet 5-HT values in male and female alcoholic patients with or without insomnia.

In line with our previous preliminary findings showing the lack of effect of various sleep disturbances on platelet MAO activity in much smaller groups of chronic alcoholic patients, combat exposed veterans with PTSD, or patients with major depressive disorder [28], we have found that the presence of early, middle or late insomnia did not change platelet MAO-B activity in male or female alcoholic patients. In contrast to our present and previously published data [28], higher platelet MAO-B activity was found in depressed patients with late insomnia [2], and in alcoholics during the recovery period after withdrawal from heavy alcohol abuse with fatigue, insomnia and reduced sleep [3] compared to corresponding controls. However, the data on the smoking status were not reported in these older studies. Platelet MAO-B activity was significantly affected by sex and age, as expected [22], but not by smoking, although the substances from the cigarette smoke reduce platelet MAO-B activity [22,31]. Platelet MAO-B activity was similar between alcoholic patients and healthy subjects, higher in male alcoholic smokers when compared to healthy male smokers, but was not significantly affected by insomnia, medication (present study), or comorbid psychiatric diagnoses [23].

The reduced prefrontal 5-HT activity was associated with disturbed sleep-wakefulness rhythm and loss of emotional control [13], while maximal 5-HT activity is achieved during waking [33]. Low central 5-HT activity is related to development of aggressive and impulsive behavior [17], that frequently occurs in chronic alcoholic patients. Although reductions in platelet 5-HT concentration, decreases in 5-HIAA levels and over-expression of the short allele of the 5-HTTLPR polymorphism [32] were found in rotation shift workers (who have disturbed sleep patterns) compared to daily workers, our present data do not confirm the hypothesis that platelet MAO-B activity (proposed to reflect the activity of the central 5-HT system [22]), might be used as a peripheral biomarker

of the insomnia. In contrast, although platelet 5-HT concentration does not reflect central 5-HT activity, platelet 5-HT concentration was significantly and inversely associated with middle insomnia in alcoholic patients.

Present and previous results [28,32] suggest that platelet 5-HT concentration might be used, after controlling for smoking and sex, as a peripheral biomarker for insomnia in alcoholism, PTSD and in rotating shift workers.
